Detailed Breakdown of Common Questions and Model Answers

Below, we delve into some typical questions from Section 38 and their comprehensive answers to exemplify how these resources aid learning.

Question 1: Describe the structure and function of the mitochondria.

Answer:

The mitochondria are double-membraned organelles found in most eukaryotic cells. They are often referred to as the "powerhouses" of the cell because they generate most of the cell's adenosine triphosphate (ATP) through a process called cellular respiration. The outer membrane is smooth and serves as a barrier, while the inner membrane is folded into structures called cristae, increasing surface area for metabolic reactions. The mitochondria contain their own DNA, enabling some autonomous replication, and play a crucial role in energy production, apoptosis, and metabolic regulation.

Question 2: Explain the process of natural selection.

Answer:

Natural selection is a mechanism of evolution where organisms with advantageous traits are more likely to survive and reproduce, passing those traits to their offspring. Over generations, this process leads to the adaptation of populations to their environments. The key steps include variation within populations, differential survival and reproduction, and inheritance of traits. Factors such as environmental pressures, mutations, and genetic drift influence this process, shaping the diversity of life on Earth.

Question 3: What is the significance of the Calvin cycle in photosynthesis?

Answer:

The Calvin cycle, also known as the light-independent reactions, takes place in the stroma of chloroplasts. Its primary function is to convert carbon dioxide into glucose using ATP and NADPH produced during the light-dependent reactions. This cycle involves three main stages: carbon

fixation, reduction, and regeneration of the acceptor molecule (ribulose biphosphate). The Calvin cycle is vital because it synthesizes organic molecules essential for plant growth and forms the foundation of the food chain.
